

# Inference of ecological networks and possibilistic dynamics based on Boolean networks from observations and prior knowledge

Loïc Paulevé, Cédric Gaucherel (AMAP, INRAe, CIRAD, Montpellier)

bioRxiv preprint: <https://www.biorxiv.org/content/10.1101/2024.07.01.601264v1>

# Context, general motivation

- From observed (qualitative) change of species abundances, *generate hypotheses* on the underlying ecological network
- *Ecological network*: trophic (predation) + competition

- Network inference: take into account *prior expert knowledge*

# Approach

## Application:

- Protist system with 6 species
- Extensive observations of *transitions* of species presence

## Methodology:

- *Link ecological networks with influence graph* of Boolean networks
- Use *BoNesis* to *infer Boolean networks* being able to reproduce transitions
- Extract ecological networks from the influence graph
- Define *optimization criteria*: sparsity vs fidelity
- Apply with *different prior knowledge*, compare results

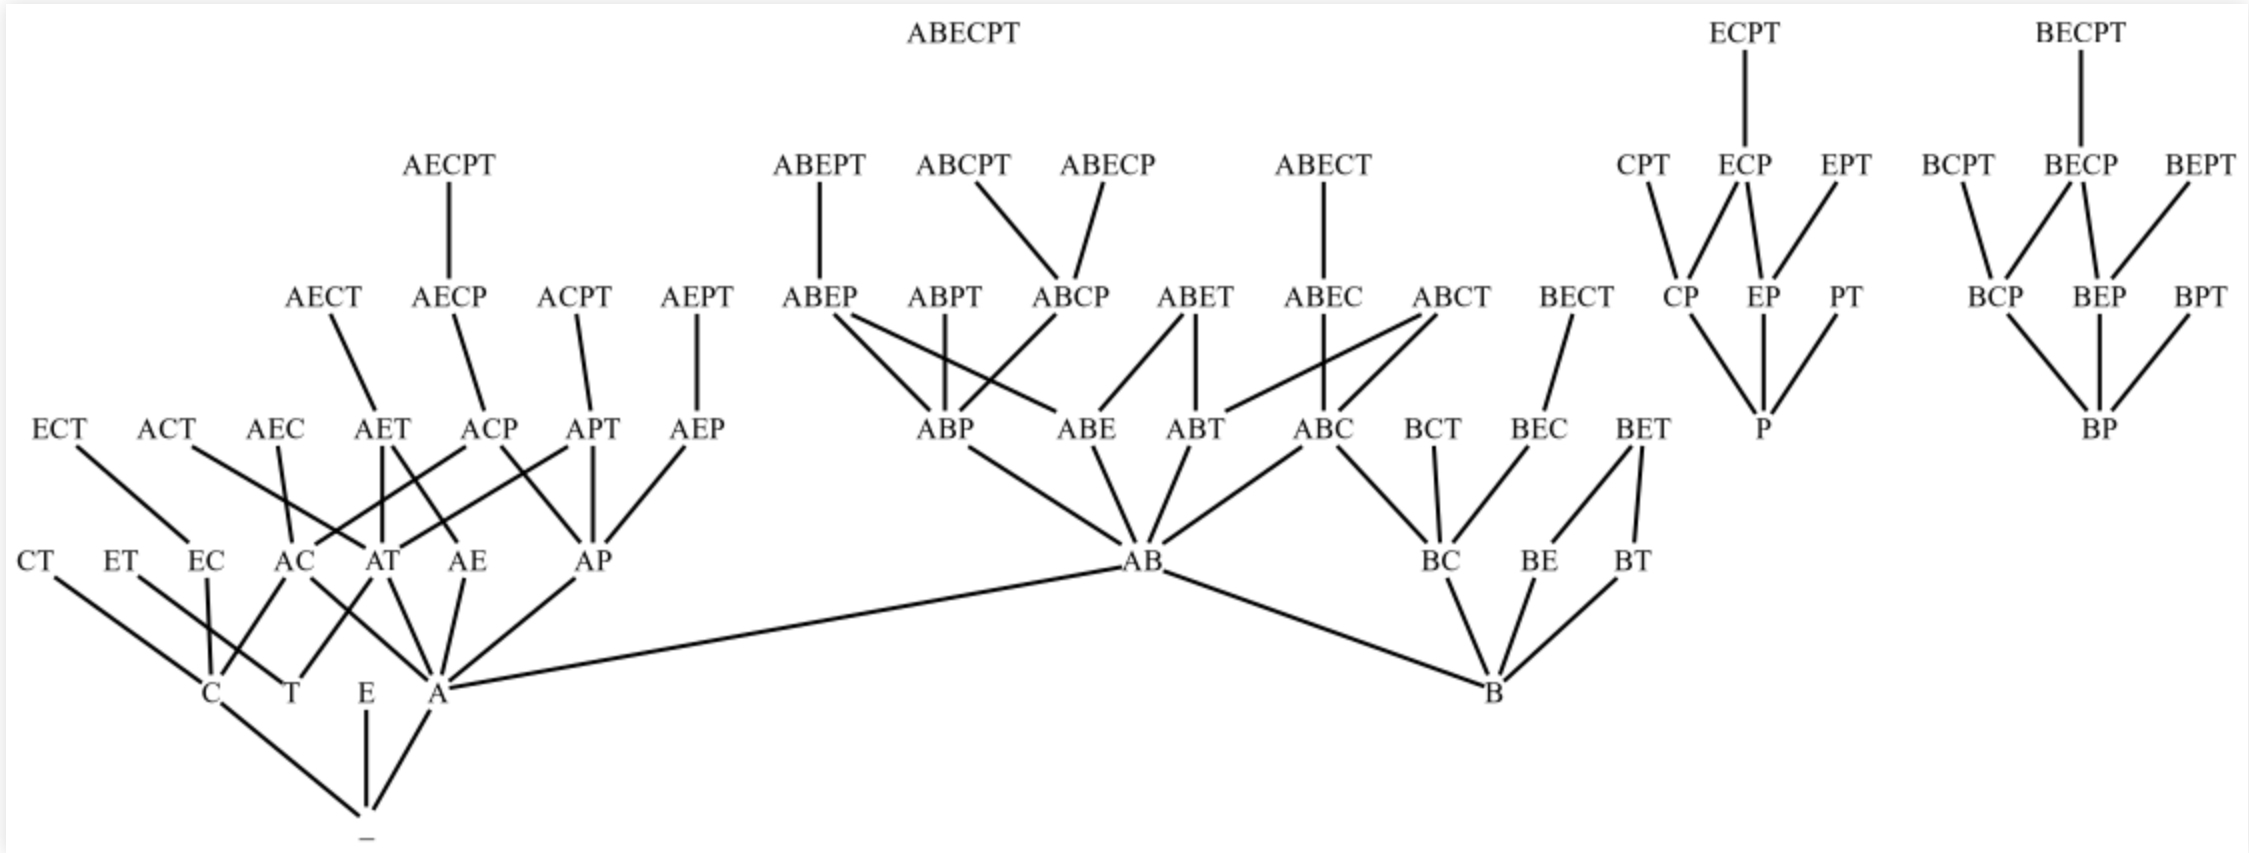

# Protist community

Seminal protist experiment published by University of Sheffield (Weatherby, Law, Warran; 1998-2006):

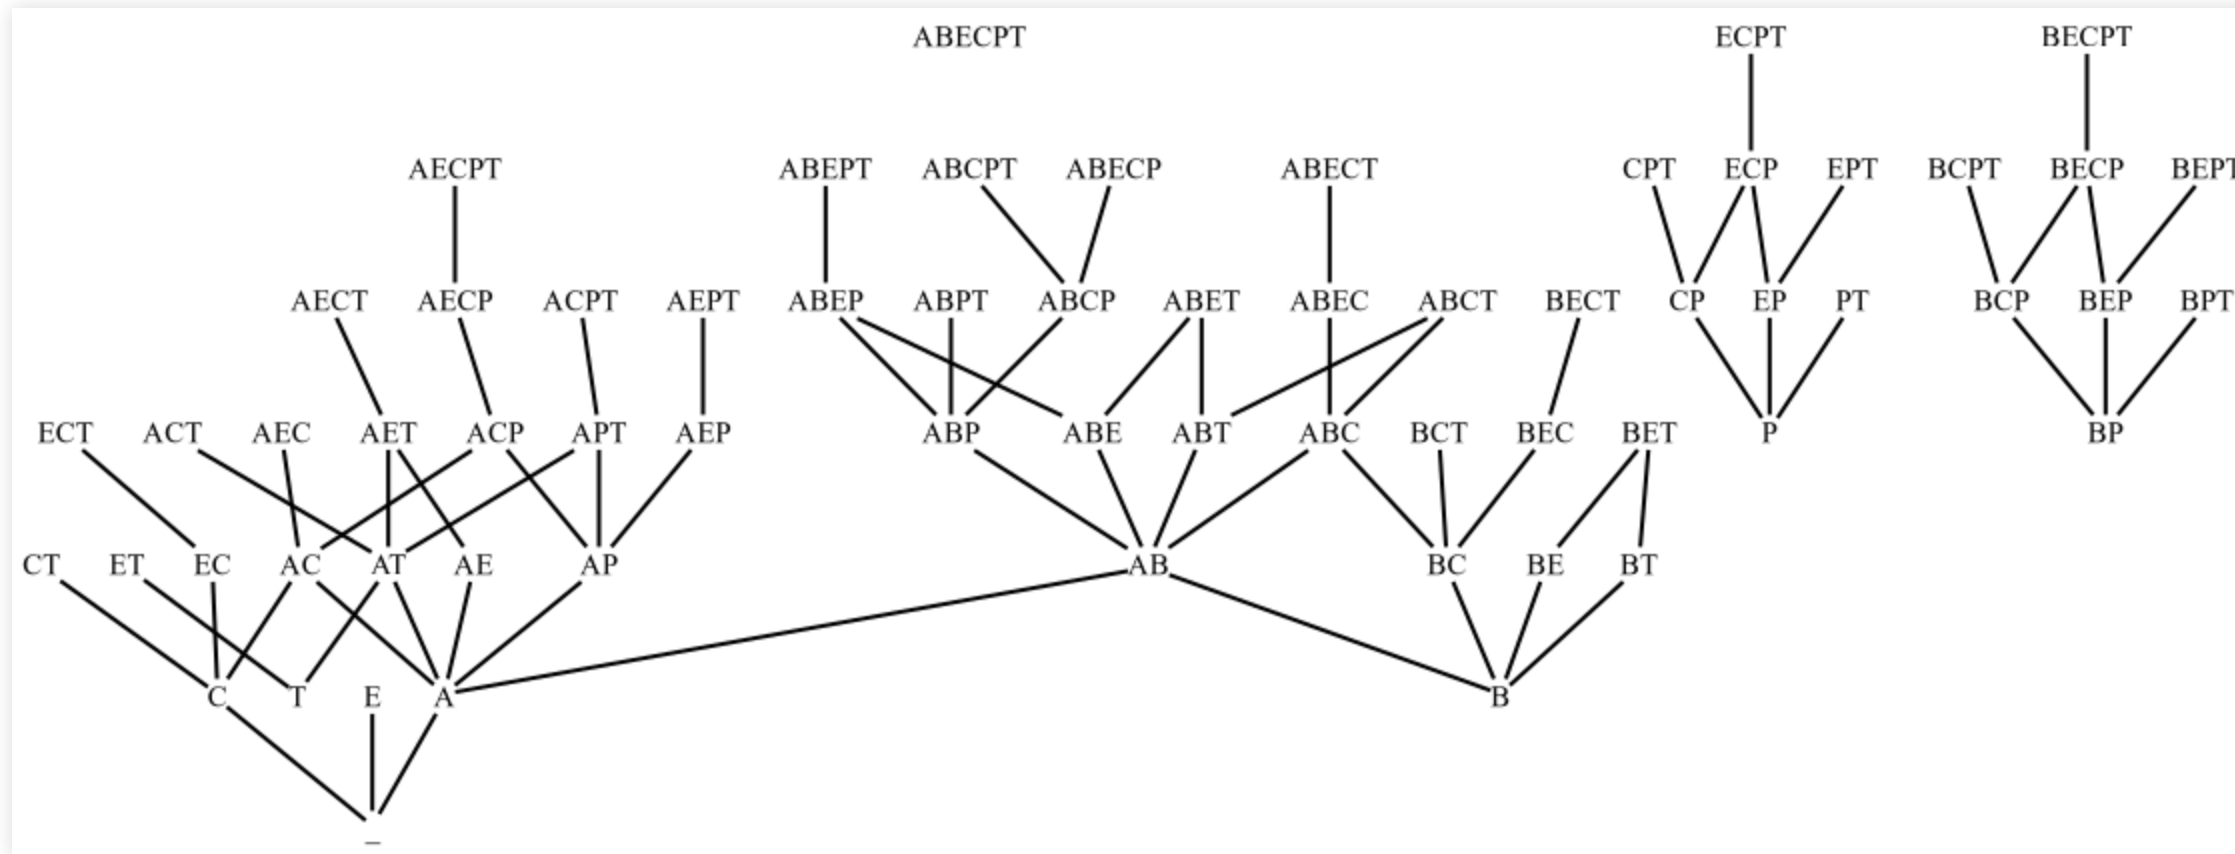

# Observed transitions

- 63 combinations of protist species have been tested and replicated (6x)
- Bacteria always present
- Measurements in time series; qualitative analysis by M. de Goër de Herve (2022):

# Dynamical properties

- Transitions are fully asynchronous (only one species disappears at a time)
- 4 steady states:  $\_$  (no survivor); B, P, BP
- From ABECPT (all), transitions are too fast to observe (uncertainty on possible transitions)

# Boolean networks

$$f_1(\mathbf{x}) = \neg \mathbf{x}_2$$

$$f_2(\mathbf{x}) = \neg \mathbf{x}_1$$

$$f_3(\mathbf{x}) = \neg \mathbf{x}_1 \wedge \mathbf{x}_2 \wedge \neg \mathbf{x}_3$$

(a) Boolean network

(b) Influence graph

(c) Asynchronous dynamics with configurations as binary vectors

(d) Asynchronous dynamics with configurations as present species, assuming species A, B, C have index 1, 2, and 3, respectively

# General objective for the inference

What do we want:

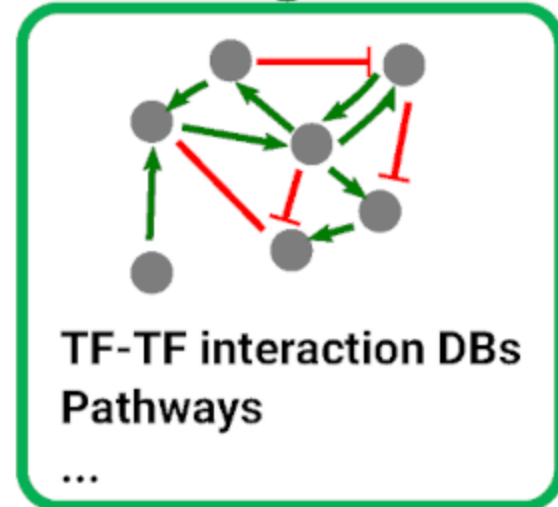

1. Boolean networks that are able to reproduce *at least* the observed transitions
  - ↳ find logic of presence/absence for each species that can explain the transitions
2. *minimize deviations* from observed transitions
  - ↳ models that predict as less as *unobserved transitions* as possible
3. sparse models: smallest (nb of edges) ecological networks

# BoNesis

## Experimental data

## Knowledge

## Biological expertise

**BoNesis - generic BN synthesis engine**

- Symbolic Artificial Intelligence, automatic reasoning (ASP)
- Scalable to real-world data (X,000 genes/cells)
- Open source (CeCiLL/GPL)

**Ensembles of Boolean networks**

**Predictions**

- Gene selection
- Key regulations
- Mutations

# BoNesis • Proof of concept on scRNA-seq data

Modeling hematopoiesis cellular differentiation processes

PhD work of  
Stéphanie Chevalier

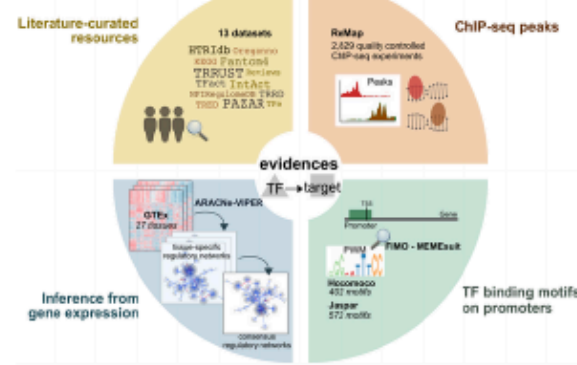

## scRNA-seq data

~4,800 nodes (proteins)  
~16,000 influences

## DoRotheA TF-TF db

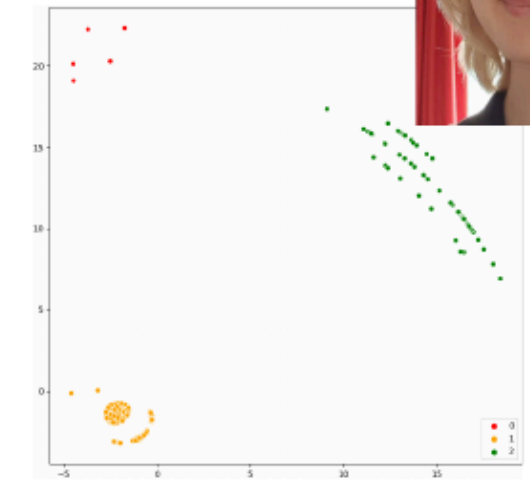

[saezlab.github.io/dorothea](https://saezlab.github.io/dorothea)

1.5 million interactions between  
1399 TFs and 27,976 target genes

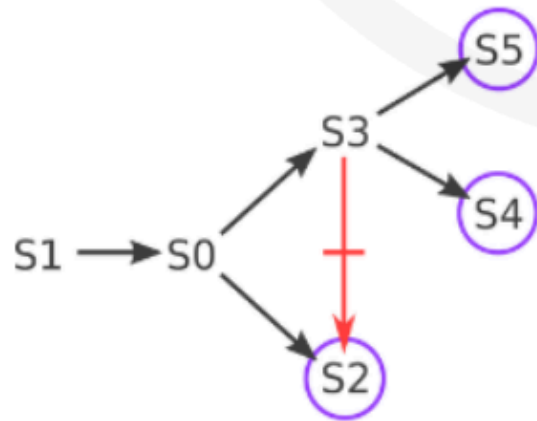

## Node selection

## Models clustering

## Boolean dynamical properties

BoNesis

## Solution sampling

## Model variability analysis

# BoNesis in a nutshell

```
dom = bonesis.InfluenceGraph(...)
data = {
  "init": {"A": 0, "B": 0, "D": 0},
  "marker": {"A": 1, "C": 1}
}
bo = BoNesis(dom, data)
x = ~bo.obs("init") # cfg matching with init
y = ~bo.obs("marker") # cfg matching with marker
bo.fixed(y) # y is a fixed point
x >= y # exists trajectory from x to y
x >> "fixedpoints" ^ {bo.obs("marker")}
# each fixed point reachable from x matches
# with marker (have A=1 and C=1)

# enumerate solutions:
for f in bo.boolean_networks():
  .....
```

<https://bnediction.github.io/bonesis>

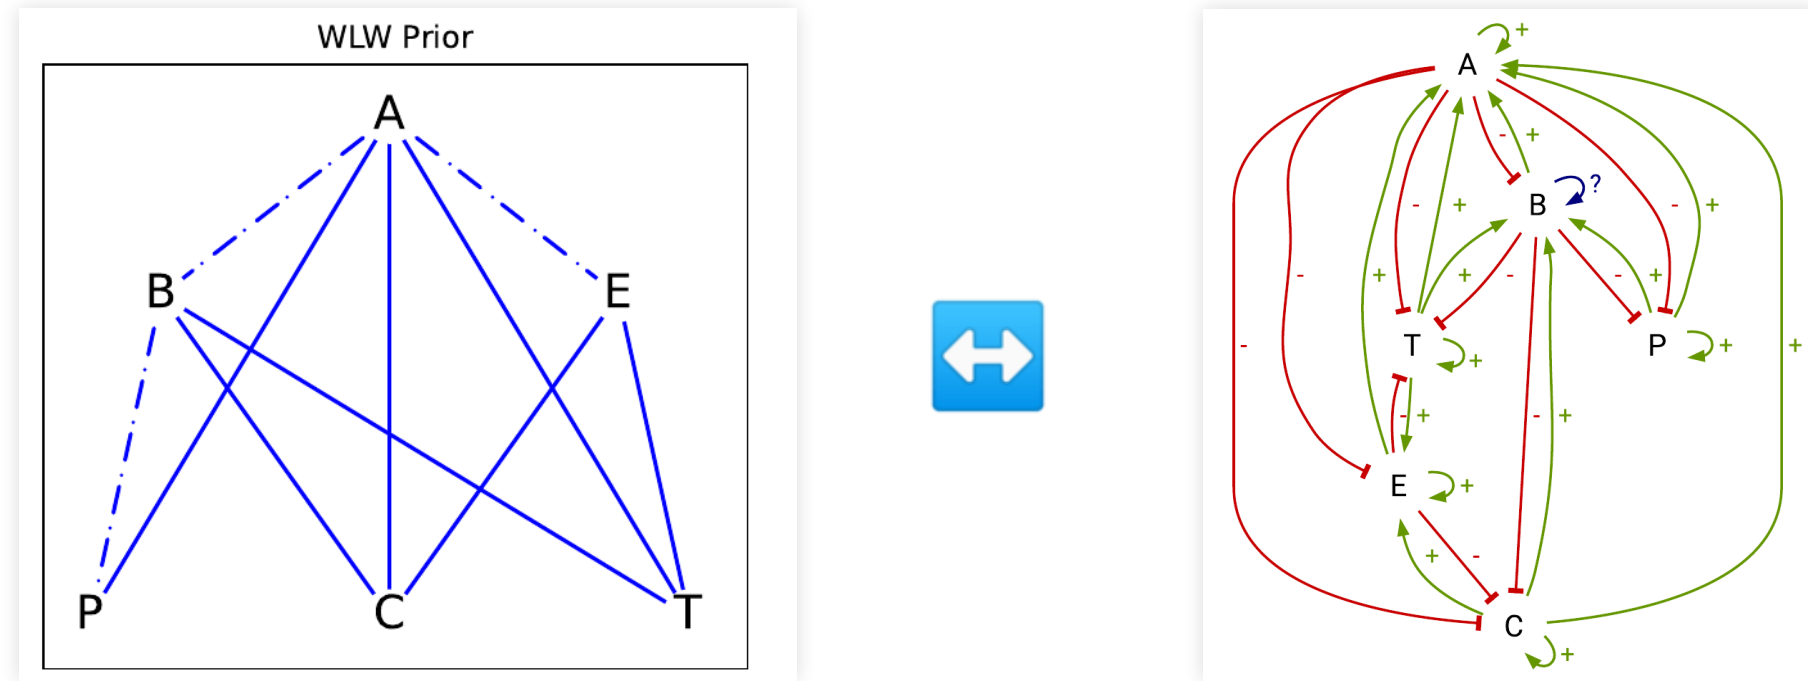

## Modeling

- 1 **Domain** of Boolean networks
  - influence graph / partially specified BN
  - single BN (model checking/control)
- 2 **Observations** binarized
  - can be partial
- 3 **Dynamical properties**
  - link configurations with observations
  - trajectories, fixed points, trap spaces, mutants, ...

## Solving

- Optimizations (BN size, error, ...)
- Different views of solutions
  - Boolean networks (w/ or w/o diversity),
  - Influence graphs, configurations, ...

# Ecological networks vs Boolean networks

- A predates B means A has a negative influence on B, and B a positive on A
- positive loops: mostly to allow for persistent disappearance  
(e.g.,  $f_A(A = 0, C = 0) = 0$  and  $f_A(A = 1, C = 0) = 1$ )
- non-sufficiency of prey (dashed edges): deny some logic functions  
(e.g.,  $f_A(x) = A \wedge E \wedge \square$ )

# Encoding in BoNesis

1. Domain of candidate Boolean networks:
  - either complete graph (zero knowledge), or subgraph of prior knowledge
  - additional structural constraints (acyclicity, sufficient trophies, ...)
2. Transitions that must be reproduced (fully-asynchronous)

```
with bo.scope_reachability(max_changes=1):  
    for x, y in obs.edges():  
        ~bo.obs(cfg_of_present(x)) >= ~bo.obs(cfg_of_present(y))
```

3. Optimization criteria (minimize non-observed transition + size of ecological network)

# Protists case study, part 1: inference from zero knowledge

Let's assume nothing on the ecological network... except it must be acyclic

# Zero-knowledge inference

Neutral: minimal model reproducing the observations; ZKMx: min deviation

WLW Prior

Neutral (deviation: 81)

ZKM1 (deviation: 18)

ZKM2 (deviation: 18)

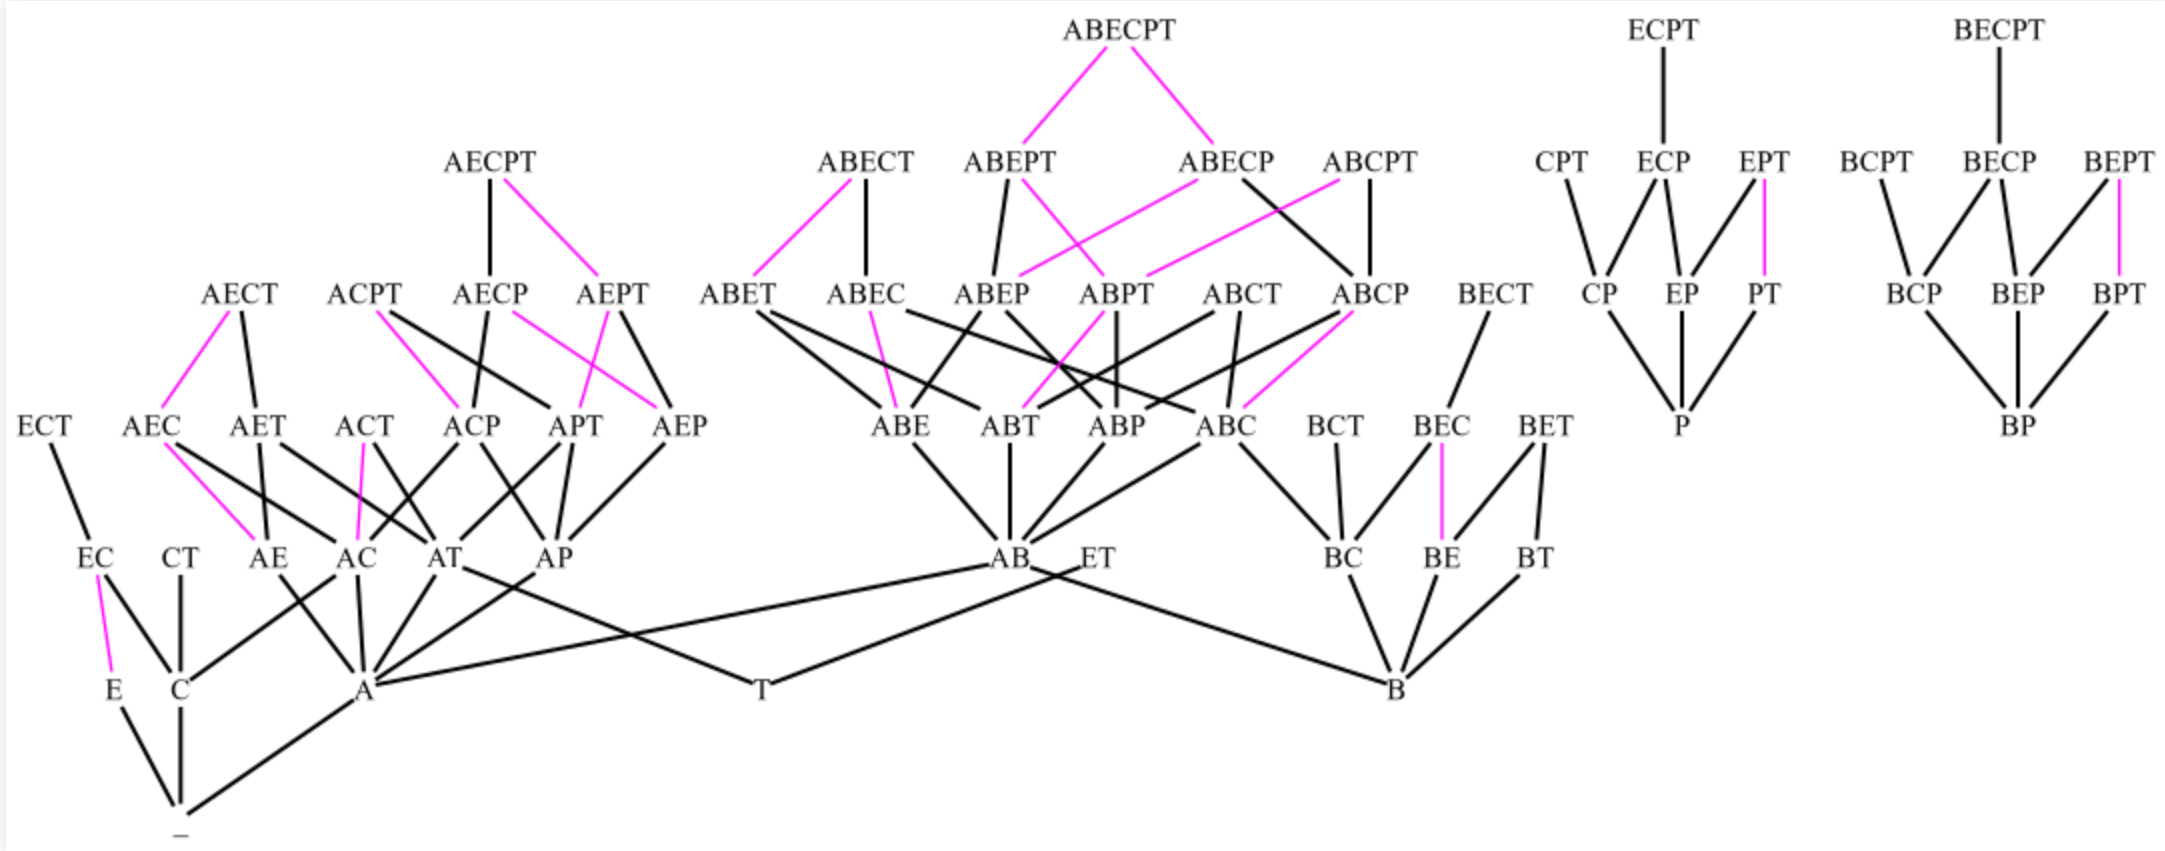

ZKM3 (deviation: 18)

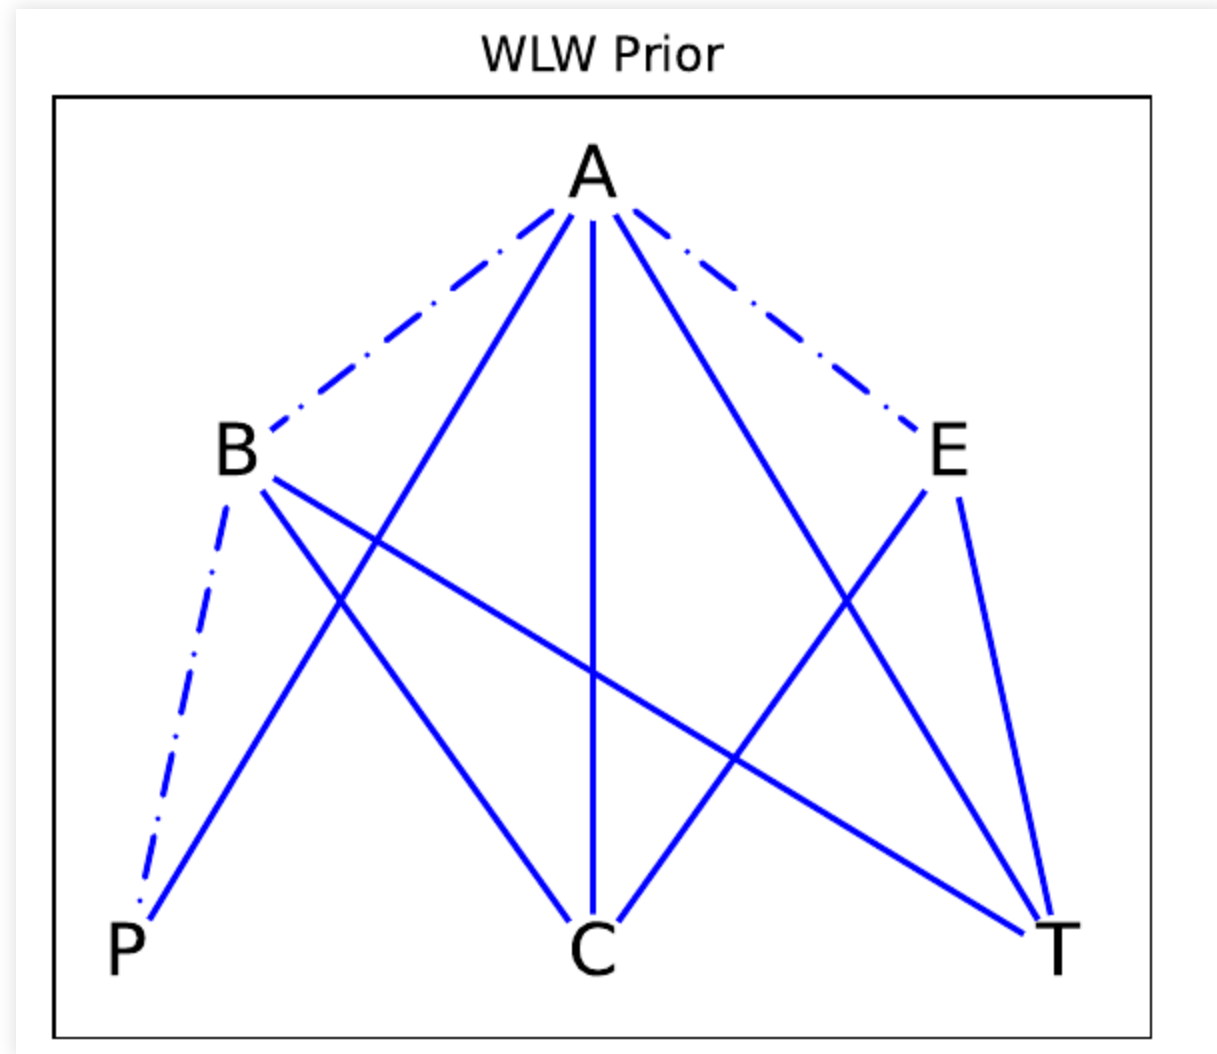

# Transitions of ZKM3

# Protists case study, part 2: integrating prior knowledge

 only employ ecological interactions deemed possible by an expert

# Prior trophic network from Weatherby, Law, and Warran

✘ UNSAT: T can survive alone, but not in presence of C or P

↻ Network is incomplete

# Extended prior trophic network

De Goër de Herve et al. (2022) proposed an extended trophic networks, coupled with potential competitions

GeA Prior

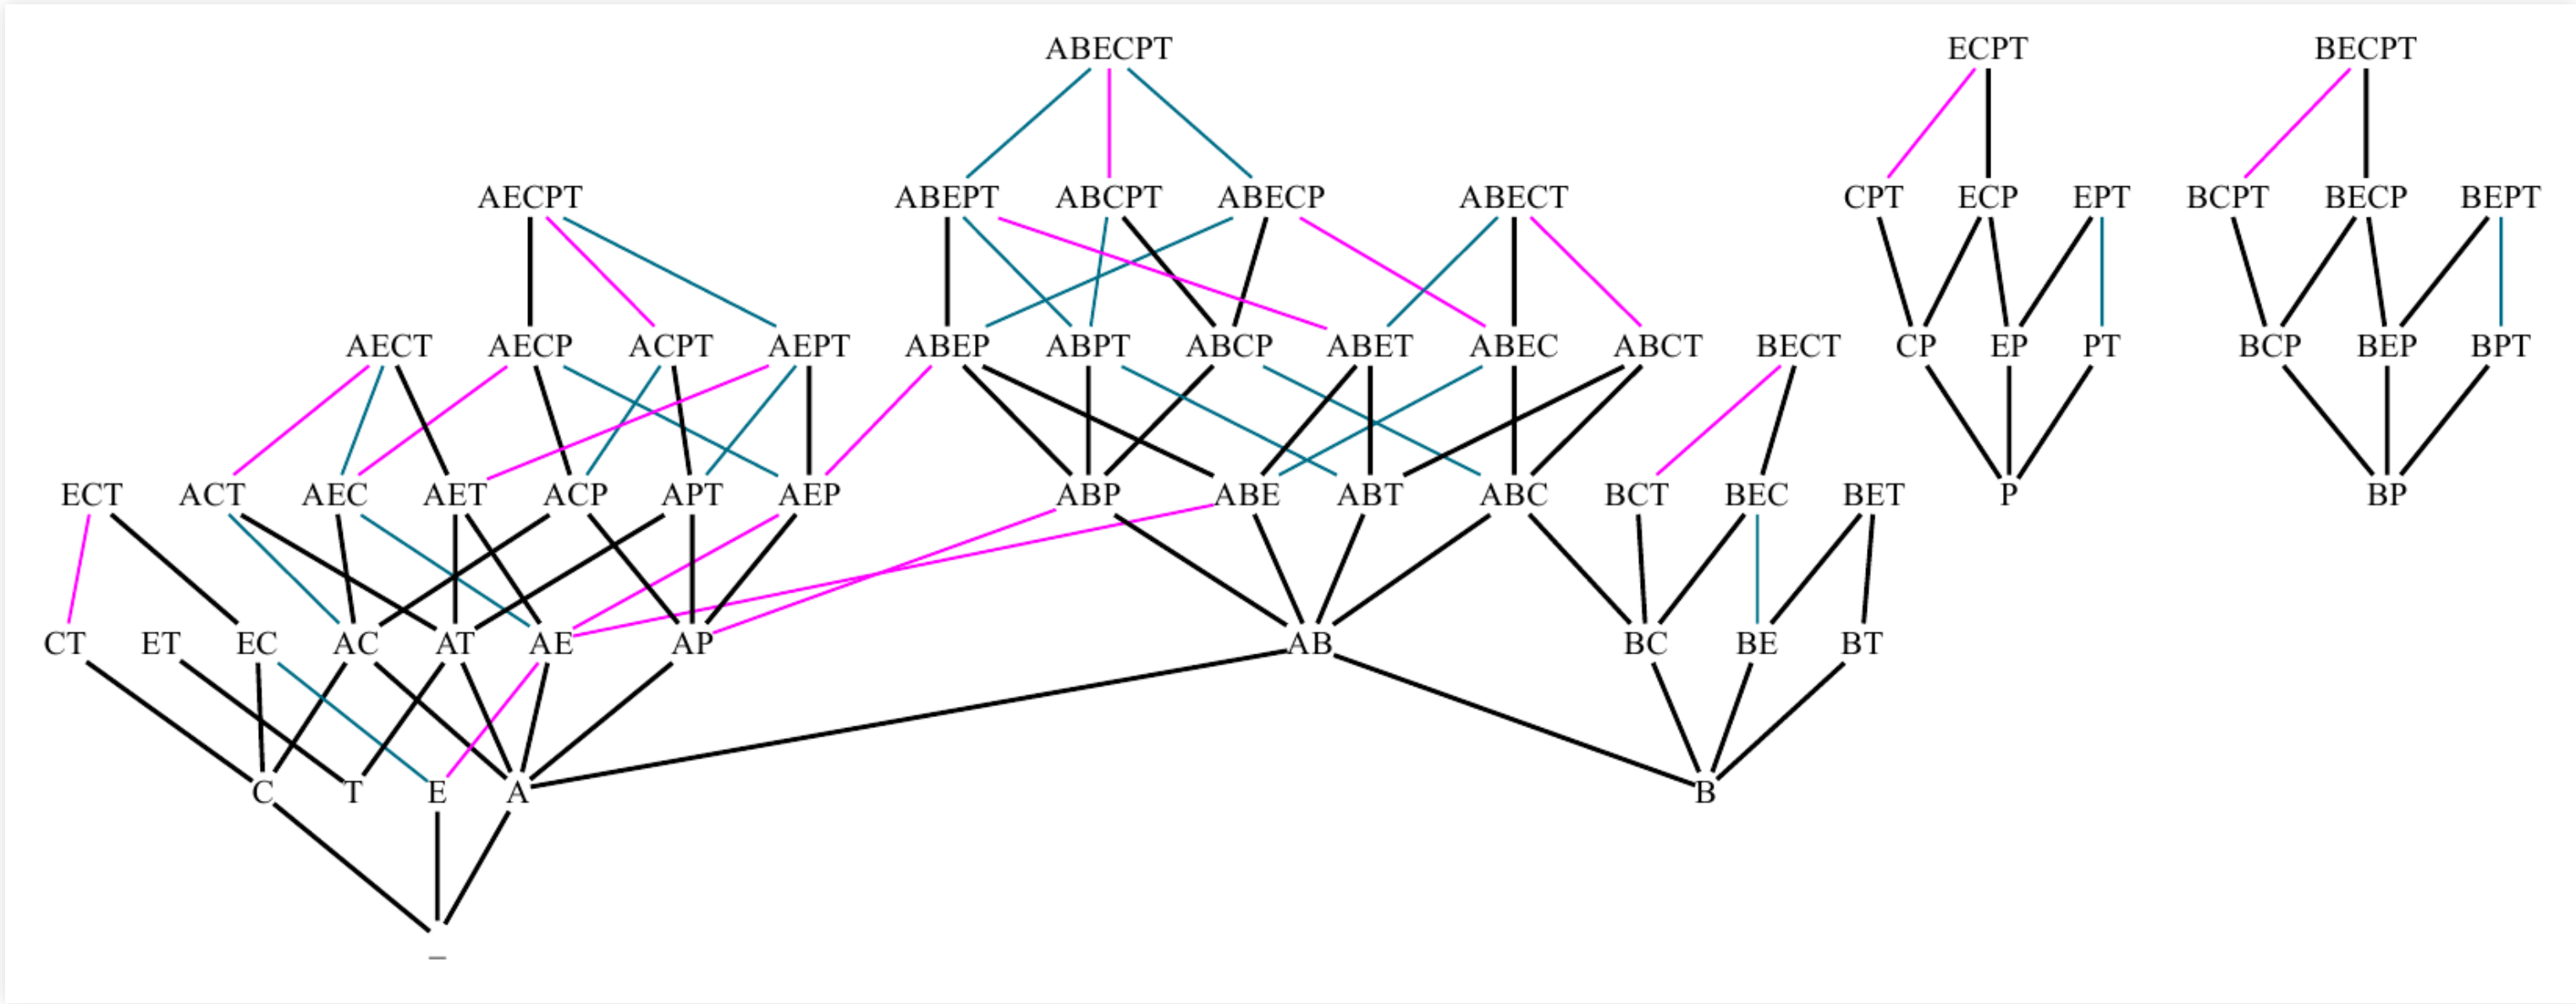

GeA best fit (deviation: 34)

ZKM3 (deviation: 18)

# ... resulting transition graph

# Discussion

## Inferred ecological networks:

- Zero-knowledge models are already quite plausible (ZKM3 fully reflect the size of the species)
- One can prove that prior knowledge can be incomplete (and point where)

## Inferred dynamical models

- Added transitions often complete *diamonds* (concurrent transitions)
- Less deviation (spurious transitions) = more complex logic/network
  - ↳ trade-off with the abstraction level: time/speed could also explain absence of transitions
  - ↳ importance of prior knowledge to *prevent overfitting*

# Discussion

## Pros:

- Easy to implement and quick to execute
- Flexibility on the specification/constraints

## Limits / applicability to other case studies

- Small system; with large systems, we need to bound the complexity of the Boolean functions
- Competition vs predation can be tricky to distinguish from Boolean rules
- Would be nice to try other systems / compare with other tools (LFIT?)
- BoNesis supports reachability, steady state, and control properties: handle more usual ecological data?
- BoNesis restricted to locally-monotone BNs; WiP to non-monotone
